	distractor: T = 60 °C (heat gained by melted ice water omitted)
11.	**Ans: C** Resonance occurs when the natural frequency of water molecules matches the frequency of the incident microwave. By changing its frequency, resonance will not occur, resulting in smaller amplitude of vibration of water molecules and therefore, lesser amount of energy absorbed by the food for it to be cooked. To warm up the food faster, the water molecules need to vibrate more to transfer more energy to the food. This can be achieved by increasing the amplitude of the incident microwave which will result in more energy being transferred from the microwave to the water molecules.
12.	**Ans: D**
