		$(20 \times 10^{-})$ $= 9.4 \times 10^{-4}$ T (2sf)
26	**B**	By RHGR, magnetic field due to long wire cuts loop wire into the page. When the loop is pulled to the right, magnetic flux linkage decreases as the magnetic field becomes weaker. By Faraday's Law, e.m.f. is induced in the loop of wire. By Lenz's law, induced current will flow in a direction to oppose the change causing it (to increase the magnetic flux linkage into the page). Induced current will flow in a clockwise direction. The vertical sections of the loop of wire will experience a magnetic force due to the magnetic field of the long wire, with a force to the left on the left side of the loop and a force to the right on the right side of the loop. Since the left side of the loop is nearer to the long wire, it experiences a greater magnetic force. Hence, the net force acting on the loop will be to the left.
