2 $s = ut + \frac{1}{2}at^2 = \frac{1}{2}at^2$ (u = 0 as balls are dropped from rest)

Displacement s of each ball increases at equal intervals s.

However, s is a quadratic function of t, so for each equal increase in s, the corresponding increase in time interval t should be smaller.

(Can try by substituting in values for yourself. E.g. s = 1 m, 2 m, 3 m and calculate each corresponding t and the increase in t)
