10	**Answer: B**
	A geostationary object must be in: - Equatorial orbit - Travelling from west to east (same direction of rotation of the Earth) - Have a period of 24 hours (and hence angular velocity) - Fixed altitude (height) from the centre of the Earth The object on Earth does not have the same radius as the geostationary object. Hence, the geostationary object cannot be orbiting with the same speed.
