19	**Answer: C**

A	Both charges are positive. Electric potential decreases as distance increases from either charge. The electric potential at point P is minimum.
B	As both charges are positive, electric potential is positive at point P.
C	**The resultant electric field between P and Y is towards X. Hence, a negative charge placed there will move towards Y (opposite direction of resultant electric field).**
D	This is only true for an isolated point charge placed at position Y.
