		increasing intensity results in more photons incident on the metal per unit time, so more electrons will be emitted.
28	**B**	When electrons are released by metal, it becomes positive. This causes the gold leaf to rise. energy of red light $= \frac{6.63\times10^{-34}\times3.00\times10^{8}}{650\times10^{-9}\times1.60\times10^{-19}} = 1.9125\ eV$ energy of red photon < minimum energy, so cannot release electrons from both metals. energy of blue light $= \frac{6.63\times10^{-34}\times3.00\times10^{8}}{450\times10^{-9}\times1.60\times10^{-19}} = 2.7625\ eV$ energy of blue photon > minimum energy of potassium, so electrons emitted. energy of blue photon < minimum energy of alumium, so cannot release electrons.
29	**A**	Alpha particle closer to nucleus deflect away more. Option B shows the alpha particle slightly further away not affected by the nucleus which is
