

		$P = (1.00 \times 10^5) / (0.0015) = (2.00 \times 10^5) / (0.0015) = 1.33 \times 10^8 \text{ Pa}$ Change in pressure = $(4.75 - 1.00) \times 10^5 = 3.75 \times 10^5 \text{ Pa} = 375 \text{ kPa}$
14	B	Higher specific heat capacity means that more energy will be needed to cool down or heat up the material. Hence, the temperature of gold will be higher than that of iron. $Mc(20+T) = 0.100c_w (40 - T)$
15	D	A: Internal energy of an ideal gas is made of sum of random distribution of KE
