

		present. The calculated value of acceleration is close to actual value of 9.81 m s^{-2} , hence accurate.
2	A	With constant acceleration while there is fuel, the rocket gains velocity at a constant rate. When the fuel is used up, the rocket experience gravitational acceleration downwards, hence slowing down till it reaches the maximum height with zero vertical velocity, before falling back down with gravitational acceleration towards the ground. Area under the v-t graph above and below the horizontal axis should be about the same.
3	A	$v^2 = u^2 + a \cdot t = 0 + at$
