Ans: C

As the normal contact force (i.e. the reading on the scale) is more than the weight of the sack, the lift must be moving upwards and its acceleration must be pointing upwards.

$$N - W = ma$$

$$N = mg + ma$$

Considering the forces acting on the sack only:

$$N - W = ma$$

$$12(9.81) - 10(9.81) = 10a$$

$$a = 1.96 \text{ m s}^{-2}$$
