

		a has increased by 0.25λ .
19	B	Using Rayleigh's criterion, $\theta_R \approx \frac{\lambda}{d}$ The smaller the value of θ_R, the better the resolution because smaller details can be resolved.

Therefore, the telescope with the best resolution is the telescope with the smallest ratio of $\frac{\lambda}{d}$.

telescope	λ/d	resolution
(i)	5.0×10^{-7}	Worst
(ii)	5.0×10^{-8}	Best
(iii)	3.3×10^{-7}	

Hence, in the order from the worst resolution to the best resolution, it will be (i), (iii), (ii).
