Minimum angle of resolution $\theta_{\min} = \frac{\lambda}{b}$ (Rayleigh criterion)

Images are resolved if the angular separation between the 2 sources is at least $\theta_{\min}$.
Since the images just failed to be resolved, θ is smaller than $\theta_{\min}$.

Option A is wrong: If aperture size b becomes smaller, $\theta_{\min}$ will become larger, and so the images will still not be resolved.

Option B is wrong: Moving the slit further from the 2 sources will decrease the angular separation of the 2 sources, so the images will still not be resolved.

Option C is wrong: Moving the screen nearer to the source has no effect on $\theta_{\min}$.

$$\lambda_G > \lambda_V$$

Using violet light will decrease $\theta_{\min}$, hence allowing θ to be larger than $\theta_{\min}$.
