

		Over a complete cycle, average power dissipation = $\frac{2R}{2} + \frac{R}{2} + \frac{4R}{2}$
29	A	$\frac{hc}{\lambda} = \Phi + eV_s \Rightarrow eV_s = \frac{hc}{\lambda} - \Phi$ So with half the wavelength, the stopping potential would be more than double the original. Intensity, $J \propto n \left(h \frac{c}{\lambda} \right)$ $n \propto J\lambda$ So, rate of photons incident on metal electrode remains unchanged.
30	D	$hc - hc - hc$
