| 2 | (a)   | A prototype space shuttle attached to a rocket stands vertically on its launching pad. The total mass of the spaceship and rocket (inclusive of the mass of a man in it and its fuel) is $8.5 \times 10^4$ kg. On ignition, gas is ejected from the rocket at a speed of $6.0 \times 10^3 \text{ m s}^{-1}$ relative to the rocket, and the fuel is consumed at a constant rate of $138 \text{ kg s}^{-1}$ . |  |

|   | (b)   | Body A of mass 2.0 kg moves towards Body B of 3.0 kg as illustrated in Fig. 2.1.                                                                                                                                                                                                                                                                                                                             |  |
|   |       |                                                                                                                                                                                                                                                                                                                                                                                                              |  |

Fig. 2.1

- (i) Explain why it is not possible for both bodies to stop at the same instant.

.....

..... [1]

There is net momentum before the collision. There will be the same momentum throughout the whole collision. Therefore it is not possible for both the nucleus to be at rest at the same time. B1

- (ii) Fig. 2.2 is a velocity-time sketch graph showing how the velocity of each body varies. The interaction between the bodies is elastic.

Label the graph to show

1. which curve is for body A, [1]

2. the times at which each body stops, [1]

3. the time at which they are at their distance of closest approach. [1]

1. Since Body A is lighter, the change in velocity is bigger. A1
2. Body A stops first then Body B. A1
3. Intersection of the two curves is the time of closest approach. A1
