		Thus, reduction in electric field strength = π^2 / Ch
21	**D**	For steady current, power dissipated in resistor = I^2R For alternating current, power dissipated = $I_{rms}^2\left(\frac{R}{2}\right)$ Since power dissipated in dc is the same as that in alternating current $I_{rms}^2\left(\frac{R}{2}\right) = I^2R$ $I_{rms} = \sqrt{2}I$
22	**A**	According to $R = \frac{\rho L}{A}$, if, as L increases, A also increases, then the increase in R will not be
