25	**C**	A: The wires carry parallel currents flowing in the same direction, creating an attractive force between the wires. B: Since the right wire is slanted, its current has a parallel vertical component that interacts with the left vertical wire, causing a non-zero attractive force between the wires. C: The vertical wire creates a magnetic field pointing into the page on its right side. With the current in the horizontal wire flowing to the right, the resulting magnetic force acts upwards. Hence, the attractive force between the two wires is zero. D: The wires carry anti-parallel currents flowing in opposite directions, creating a repulsive force between the wires.
26	**D**	magnetic flux linkage = $N \times$ component of flux density normal to area $\times$ area
