

23	Ans: D As the long straight wire moves towards the flat coil, the magnetic flux density in the area enclosed by the coil increases. Since $B = \frac{\mu_0 I}{2\pi d}$, for each speed, magnetic flux density inside the coil increases at an increasing rate. This results in the increasing rate of change of magnetic flux linkage leading to increasing induced e.m.f. in the coil. Thus, current increases.
24	Ans: C
