27	B	When p.d. across E and F are zero, the electrode with a lower work function will emit more electrons upon illumination – electrode F. When there is a net electron flowing from F to E, a current flows from E to F will be positive in graph. To have a zero current, the voltage of electrode F with lower work function should be made more positive with respect to electrode E; i.e. voltage of E with respect to F is negative when current is zero.
28	D	$AF = [hc/(60 \times 10^{-12}) - hc/(70 \times 10^{-12})] / (1.6 \times 10^{-19}) = 2 \text{ keV}$
