12 Two polarising filters, P and Q, are placed in front of a light sensor. Their transmission axes are initially parallel. Unpolarised light passes through them and the sensor records an intensity I.

Filter Q is then rotated while filter P remains fixed.
Which angle through which Q may be rotated would reduce the detected intensity by 36%?

A 23º **B** 37º **C** 50º **D** 53º
