

4a	<i>Polarisation</i> is where the <u>oscillations</u> in a wave are confined to one <u>direction</u> only in a plane normal to the <u>direction of transfer of energy</u> of the wave. OR <i>Oscillations</i> occur only in one <u>plane</u>, <u>parallel</u> to the <u>direction of energy transfer</u>.	E	B1
4b	(A polarised wave vibrates in a single plane in space.) Since longitudinal waves <u>vibrate along</u> their <u>axis of propagation</u>, it is not possible to polarise a longitudinal wave. Hence, only transverse waves can be polarised as it <u>vibrates perpendicular</u> to its <u>axis of propagation</u>.	A	B1 B1
4c	Angle between <u>axis of polarisation</u> between <u>images</u> is 90°. Angle between <u>axis of polarisation</u> between <u>left and right lenses</u> is 90°. Angle of polarisation of each image needs to <u>match angle of polarising axis</u> of the lens for the appropriate eye.	D	B1 B1 B1
4d	(Since the plane of the images are perpendicular to each other), the two images are never added together <u>in either eye</u>.	D	B1

5ai	The incident wave reflects at the top of the tube	A	B1
