16 An optical telescope received yellow light of wavelength 6×10^{-7} m from two yellow stars which are 1×10^{11} m apart and can just be resolved by the telescope.

The two stars are 6×10^{16} m from the telescope.

Which statement is **incorrect**?

A The aperture of the telescope has a diameter of about 0.4 m.

B The resolving power of the telescope depends on both the wavelength of light received and the aperture diameter of the telescope.

C The telescope receiving red light of wavelength 7×10^{-7} m can be used to resolve two red stars of the same separation and distance from the telescope as the two yellow stars.

D The telescope receiving yellow light of wavelength 6×10^{-7} m can be used to resolve another pair of yellow stars that are separated by 3×10^{-6} radians.
