

2a	As the sky-diver picks up speed, air resistance increases, the resultant force decreases and hence the acceleration decreases.	B1 B1
2b	(Since the sky-diver starts from rest), there is no air resistance initially / the only force he experiences is his weight, hence his initial acceleration is equal to 9.81 m s^{-2} .	M1 A1
2c	Terminal velocity is the area under the $a-t$ graph (by using trapezium rule/counting squares)	A1
2d	Correct shape start with zero gradient and ends with constant gradient from about $t = 24.0 \text{ s}$	M1 A1
