

23	Answer: A
	$I = \frac{\varepsilon}{R} = \frac{\Delta BA}{\Delta t} \left(\frac{1}{R} \right) = \frac{(4.0 \times 10^{-5}) \sin 50 \left(\pi \left(\frac{0.50}{2} \right)^2 \right)}{2.0} \left(\frac{1}{3.0} \right) = 1.0 \times 10^{-6} \text{ A}$ The current remains constant as the rate of change of flux is constant.
