

13	The specific latent heat of vaporisation of water at 20 °C is appreciably greater than the value at 100 °C. This is because	
	A	the specific latent heat at 20 °C includes the energy necessary to raise the temperature of one kilogram of water from 20 °C to 100 °C.
	B	more work must be done in expanding the water vapour against atmospheric pressure at 20 °C than at 100 °C.
	C	the molecules in the liquid are more tightly bound to one another at 20 °C than at 100 °C.
	D	vaporisation of water can only take place at 100 °C.

	Ans: C
