

		VV
28	B	The peaks will remain the same as these are characteristic of the target metal. If the p.d. is increased, the electrons are fired with greater kinetic energy at the target metal, which means that more energetic X-rays can be produced. The cutoff wavelength will decrease, because $eV_{AC} = \frac{hc}{\lambda_{\min}}$.
29	D	Original activity is $180 \text{ counts s}^{-1}$ after deducting background count. After 10 hours
